

FIN ST732–ST821

Current-Strict Total Declared-Class No-Go
and Conditional Effective Physics

30 August 2026

New physics is allowed as an explicit conditional construction. It is not silently promoted to strict derivation. No laboratory or external-review evidence is introduced.

Abstract

ST732–ST821 test whether the conditional causal-wave/ $3 + 1$ /Maxwell bridge can be selected by existing FIN information, variational, categorical or operational principles. Fixed locality, edge cost, trace stationarity, quadratic penalties and minimum-description principles can select the zero-rate tower only after importing a prior. Maximum resonance favors increasing refinement stiffness instead of a finite selector. Coarse Shannon, spectral and Green data are exactly constant on hidden refinement fibers.

Categorically, the missing bridge decomposes into at least seven independent fibers: refinement, clock grading, spatial dimension, gauge complex, calibration, orientation and empirical record. No natural global section is exported. Adding a joint action, strict convexity, Bayesian prior, bootstrap or self-consistency does not solve provenance: any desired section can be encoded as a potential minimum or fixed point. A single deeper object remains possible only if it carries all seven charges, derives its coupling law, produces a unique natural section and makes held-out predictions.

The final theorem is a total no-go for the declared current-strict class: no deterministic construction invariant under current coarse spectral/Green equivalences, and using no new fine, charged or operational datum, uniquely exports physical causal-light/ $3 + 1$ /Maxwell theory. This is not an absolute no-go for future FIN. A richer nadsoliton source or new fine/empirical datum can evade it. The minimal conditional theory $A_{12} + R + T + D + G + C + O + S$ remains coherent and falsifiable in principle, but strict physics and evidence are absent.

1 Main theorem

Theorem 1.1 (Current-strict declared-class total no-go). *Within constructions satisfying all of the following:*

1. *input is the current finite radial strict core and its spectral/Green/dual calculus;*
2. *construction is invariant on established coarse-equivalence fibers;*
3. *construction is deterministic and natural;*
4. *no new fine, charged, dimensional, oriented or operational datum is added;*

there is no unique export of physical causal-light, $3 + 1$ Maxwell, calibrated clocks/units and empirical records.

The proof is by independent counterexample fibers: exact refinements with different speeds, product carriers of different dimensions, distinct gauge complexes over one scalar Laplacian, incompatible clock grades, positive calibration torsors, paired orientations and multiple apparatus/record realizations.

The theorem is scoped. It does not rule out a richer strict nadsoliton object outside current inputs.

2 Round I: ST732–ST746

Uniform fixed-range locality and exact scale-shift self-similarity conditionally select the zero-rate tower. Neither is sourced by the endpoint. Complete coarse Green–Schur data are constant on the rate fiber. Conditional strong wave convergence and uniform outside-cone decay can then be proved, but the 3D carrier, Lorentz representation, gauge complex, Maxwell coefficients, photon interface, two physical clocks and anchor remain additional.

3 Round II: ST747–ST761

Selection principles were adversarially compared:

Principle	Selected behavior	Status
positive edge cost	$q = 0$	prior-dependent
trace stationarity	$q = 0$	conditional
quadratic penalty	$q = \max(0, J/\gamma)$	source-dependent
MDL	depends on coding language	noncanonical
maximum resonance	increasing q	no finite optimum
bare minimality	$D = 1$, scalar, no gauge	conflicts with target physics

Thus no prior-independent informational/variational selector was found in the declared class.

4 Round III: ST762–ST776

A fail-closed operational transfer packet was constructed: nuisance cover, two-clock slopes, polarization leakage, Gauss residual, causal-tail exponent, external anchor hashes, blind feature extraction, one-shot scoring, out-of-library stop and provider/registrar/analyst separation. Synthetic power is adequate in the frozen fixture; every physical apparatus/custody row remains open.

5 Round IV: ST777–ST791

The bridge is a product of seven fibrations:

$$\mathcal{F}_R \times \mathcal{F}_T \times \mathcal{F}_D \times \mathcal{F}_G \times \mathcal{F}_C \times \mathcal{F}_O \times \mathcal{F}_S.$$

There is no natural section for speed, dimension, gauge, scale or orientation from current base data. Restricting to a local scale-stationary subcategory gives a conditional zero section. The hypothesis of one missing scalar/object is refuted for the present product structure; a new coupled object can still replace the product if it derives all charges and relations.

6 Round V: ST792–ST806

Joint action and bootstrap strategies fail provenance tests:

- for any target x_* , $V(x) = \|x - x_*\|^2$ uniquely selects it;
- strict convexity supplies uniqueness, not location or physical meaning;
- $x = F(x)$ proves consistency only after F is supplied;
- coarse likelihood is constant along hidden fibers, leaving posterior prior-dependent;
- coarse Fisher geometry has null directions along exact fibers.

A one-object theory becomes meaningful only with a restricted natural law, unique solution, operational calibration and held-out transfer.

7 Round VI: ST807–ST821

The minimal conditional bridge is

$$\boxed{A_{12} + R + T + D + G + C + O + S}.$$

Removing any package restores a proved loss:

	Package	Loss
R	local refinement/coordinates	speed fiber, no selected continuum
T	two clock grades	single-clock no-go
D	spatial carrier	dimension fiber
G	gauge/Maxwell data	scalar-only dynamics
C	independent calibration	no SI prediction
O	operations/records	no empirical map
S	state/orientation	no branch/helicity provenance

Conditioned predictions include $\nu = 2$, clock exponents $(2, 1)$, $O(a^2)$ anisotropy/boost defects, two polarizations, Gauss constraint, locality-class tails and exact coarse/fine rate separation. These are falsifiable after the bridge is supplied.

8 Final scientific interpretation

[PROVEN] FIN has a coherent finite spectral-information core and rigorous no-go map.

[CONDITIONAL] FIN admits a local causal-wave and $3 + 1$ Maxwell scaffold after explicit packages.

[BLOCKED] Current FIN does not source those packages, does not predict SI c , photon/charge, apparatus or nature records, and is not a strict ToE.

The deepest surviving interpretation is therefore an informational spectral foundation with a precisely typed conditional physics interface. Truth requires maintaining the boundary between construction and provenance.

9 Recommended next programmes

Priority should be given only to genuinely new inputs:

1. a strict formula-level locality/refinement source;
2. one coupled object carrying all seven bridge charges;
3. full-energy cone theorem and 3D/Lorentz source;
4. gauge-complex and Maxwell-coefficient provenance;
5. physical two-clock and noncircular-anchor experiment;
6. independent evidence gate.

A Reproducibility

The authoritative files are the six result packets from `FIN_ST732_ST746_Results.json` through `FIN_ST807_ST821_Results.json`, their scripts/summaries and the combined packet-hash test.

B Nonclaims

No laboratory result, external audit, legacy bridge/role transfer, physical SI speed, photon, Standard Model, gravity, L_{total} or ToE closure follows. All future PDFs remain English.
